

**AMENDMENTS TO THE CLAIMS**

Please amend claim 4 as follows:

1. (ORIGINAL) A secure processor, comprising:
  - a key register including non-volatile memory stored with key data;
  - a key counter configured to indicate a bit position of the key data stored in the key register to access the key data bit by bit;
  - a digest register configured to be stored with digest data to be used for digital signature; and
  - a gate configured to output 1 for the content of the digest register when the corresponding bit of the key data accessed by the key counter is 0 and output the content of the digest register as is when the bit of the key data is 1;wherein no path for reading all data out from the outside is prepared for the key register, and the secure processor further comprises a plurality of signature dedicated instructions for controlling the key register, the key counter, and the digest register to obtain a digital signature based on the digest data, as well as general instructions.
2. (ORIGINAL) The secure processor according to Claim 1, further comprising:
  - a general mode and a security mode as processor running modes;
  - a security register configured to indicate the security mode; and
  - a general instruction for setting a security mode and a signature dedicated instruction for resetting the same; whereinthe general instruction is effective during the general mode while the signature dedicated instruction is effective during the security mode.
3. (ORIGINAL) The secure processor according to Claim 2, wherein
  - the instruction for setting the security mode causes to set the security register and initializes the key counter to 1023 at the same time; and
  - the signature dedicated instruction causes to decrease the key counter by one at the same time when an instruction for conducting signature calculation for one bit of the

key register, and causes to reset the security mode only when the key counter is 0 resulting from the signature calculation progressing bit by bit.

4. (AMENDED) The secure processor according to Claim 3, further comprising a means for detecting that each 16 bits of digest data stored in the digest register includes at least one '1'; wherein the instruction for setting the security mode causes to initialize the key counter when at least one '1' is included in each 16 bits, and causes to prevent change in data in the digest register after the security register is set.

5. (AMENDED) The secure processor according to ~~either~~ Claim 3 ~~or~~ 4, wherein

the secure processor is connected to main memory; and the signature dedicated instruction causes to store results of digital signature calculation only in a specific area of the main memory and write the results of digital signature calculation over previous calculation results.

6. (AMENDED) An IC card including a secure processor according to either of Claims 1 to 5 and 7.

7. (NEW) The secure processor according to Claim 4, wherein  
the secure processor is connected to main memory; and the signature dedicated instruction causes to store results of digital signature calculation only in a specific area of the main memory and write the results of digital signature calculation over previous calculation results.
